## ABSTRACT:

Methods and apparatus for monitoring, for example, accounts receivable, accounts payable, inventory, trading partners, chart of accounts, invoices, and/or payments, using a process management and workflow system coupled to a data repository are described. In one embodiment, the process management and workflow system is configured to be coupled to an accounting system by a communications link, and communicates with the accounting system via the communication link, authenticates the validity of the accounting system, receives financial information from the accounting system, extracts data from the financial information, and loads the extracted data into said data repository.

## ABSTRACT:

Methods and Apparatus for monitoring collateral risk are described. In one embodiment, the method includes monitoring, for example, accounts receivable, accounts payable, inventory, trading partners, chart of accounts, invoices, and/or payments of a client using a process management and workflow system coupled to a data repository. Specifically, and in an exemplary embodiment, the method includes receiving financial information, extracting data from the financial information, evaluating current collateral information based on the data, and evaluating current credit status.

L48: Entry 155 of 185

File: USPT

Apr 16, 2002

DOCUMENT-IDENTIFIER: US 6373950 B1

TITLE: System, method and article of manufacture for transmitting messages within messages utilizing an extensible, flexible architecture

Brief Summary Text (16):

Banks desire an Internet payment solution that emulates existing Point of Sale (POS) applications that are currently installed on their host computers, and require minimal changes to their host systems. This is a critical requirement since any downtime for a banks host computer system represents an enormous expense. Currently, VeriFone supports over fourteen hundred different payment-related applications. The large number of applications is necessary to accommodate a wide variety of host message formats, diverse methods for communicating to a variety of hosts with different dial-up and direct-connect schemes, and different certification around the world. In addition, there are a wide variety of business processes that dictate how a Point of Sale (POS) terminal queries a user for data and subsequently displays the data. Also, various vertical market segments, such as hotels, car rental agencies, restaurants, retail sales, mail sales/telephone sales require interfaces for different types of data to be entered, and provide different discount rates to merchants for complying with various data types. Moreover, a plethora of report generation mechanisms and formats are utilized by merchants that banking organizations work with.

Brief Summary Text (19):

As discussed above, the current state-of-the-art in Internet based payment processing is a protocol referred to as SET. Since the SET messages are uniform across all implementations, banks cannot differentiate themselves in any reasonable way. Also, since SET is not a proper superset of all protocols utilized today, there are bank protocols which cannot be mapped or translated into SET because they require data elements for which SET has no placeholder. Further, SET only handles the message types directly related to authorizing and capturing credit card transactions and adjustments to these authorizations or captures. In a typical POS terminal in the physical world, these messages comprise almost the entire volume of the total number of messages between the merchant and the authorizing bank, but only half of the total number of different message types. These message types, which are used infrequently, but which are critical to the operation of the POS terminal must be supported for proper transaction processing.

Detailed Description Text (40):

Thus, through the development of frameworks for solutions to various problems and programming tasks, significant reductions in the design and development effort for software can be achieved. A preferred embodiment of the invention utilizes HyperText Markup Language (HTML) to implement documents on the Internet together with a general-purpose secure communication protocol for a transport medium between the client and the merchant. HTTP or other protocols could be readily substituted for HTML without undue experimentation. Information on these products is available in T. Berners-Lee, D. Connolly, "RFC 1866: Hypertext Markup Language--2.0" (November 1995); and R. Fielding, H. Frystyk, T. Berners-Lee, J. Gettys and J. C. Mogul, "Hypertext Transfer Protocol--HTTP/1.1: HTTP Working Group Internet Draft" (May 2, 1996). HTML is a simple data format used to create hypertext documents that are portable from one platform to another. HTML documents are SGML documents with generic semantics that are appropriate for representing information from a wide range of domains. HTML has been in use by the World-Wide Web global information initiative since 1990. HTML is an application of ISO Standard 8879: 1986 Information Processing Text and Office Systems; Standard Generalized Markup Language (SGML).

Detailed Description Text (52):

Sun's Java language has emerged as an industry-recognized language for "programming the Internet." Sun defines Java as: "a simple, object-oriented, distributed, interpreted, robust,

secure, architecture-neutral, portable, high-performance, multithreaded, dynamic, buzzword-compliant, general-purpose programming language. Java supports programming for the Internet in the form of platform-independent Java applets." Java applets are small, specialized applications that comply with Sun's Java Application Programming Interface (API) allowing developers to add "interactive content" to Web documents (e.g. simple animations, page adornments, basic games, etc.). Applets execute within a Java-compatible browser (e.g. Netscape Navigator) by copying code from the server to client. From a language standpoint, Java's core feature set is based on C++. Sun's Java literature states that Java is basically "C++, with extensions from Objective C for more dynamic method resolution".

Detailed Description Text (126):

In function block 1440, merchant computer system 130 validates payment gateway digital signature 1325. Merchant computer system 130 performs this validation by calculating a message digest over the contents of the combined basic authorization request 1310 and the signature public key certificate 1320. Merchant computer system 130 then decrypts digital signature 1325 to obtain a copy of the equivalent message digest calculated by payment gateway computer system 140 in function block 1255. If the two message digests are equal, the digital signature 1325 is validated. If validation fails, merchant computer system 130 concludes that the authorization response is counterfeit and raises an error condition. In function block 1450, merchant computer system 130 stores capture response for later use in by legacy system accounting programs, e.g. to perform reconciliation between the merchant operating merchant computer system 130 and the financial institution from whom payment was requested, thereby completing the transaction. The system of the present invention permits immediate deployment of a secure payment technology architecture such as the SET architecture without first establishing a public-key encryption infrastructure for use by consumers. It thereby permits immediate use of SET-compliant transaction processing without the need for consumers to migrate to SET-compliant application software.

Detailed Description Text (146):

This section describes the GET and POST arguments that are associated with each transaction URL. It also describes the results from the GET and POST methods. For URLs that produce any kind of results, the following fields are present in the HTML document that is returned by the vPOS Terminal Cartridge:

Detailed Description Text (147):

For URLs that deal with financial transactions, the following fields are present in the HTML document that is returned by the vPOS terminal cartridge:

Detailed Description Text (151):

GET Results: Retrieves the transaction totals for the merchant. Currently, the total is returned as an HTML document. The transaction totals currently returned are:

Detailed Description Text (157):

POST Results: On success, pvstxnNum and txnAdjustedAmount are presented in the HTML document, in addition to the transaction fields described above.

Detailed Description Text (163):

POST Results: On success, an HTML document that contains the transaction fields described above is returned. On failure, an HTML document that contains the reason for the failure of the transaction is returned. The transaction is logged into a vPOS Terminal transaction log for both instances.

Detailed Description Text (169):

POST Results: On success, an HTML document that contains the transaction fields is returned. On failure, an HTML document that contains the reason for the failure of the transaction is returned. The transaction is logged into vPOS Terminal transaction log for both instances.

Detailed Description Text (178):

GET Results: The GET method retrieves the transactions that have been batched in the vPOS terminal for future reconciliation. The batch can be cleared from the vPOS terminal after a manual reconciliation between the acquirer and the vPOS. The batch data is retrieved as a set of records and is formatted as a table in the HTML document. The following fields are present in a typical record:

Detailed Description Text (207):

POST Results: On success, pvsTxnNum is presented in the HTML document. On failure, an HTML document is returned that contains the reason for the failure of the transaction.

Detailed Description Text (228):

POST Results: On success, an HTML document that contains the transaction fields described in Section 4.1 is returned. On failure, an HTML document that contains the reason for the failure of the transaction is returned. The transaction is logged into vPOS terminal transaction log for both instances.

Detailed Description Text (250):

POST Results: On success, pvsTxnNum is presented in the HTML document. On failure, an HTML document is returned that contains the reason for the failure of the transaction.

Detailed Description Text (262):

POST Results: On success, pvsTxnNum is presented in the HTML document, in addition to

Detailed Description Text (266):

GET Results: On success, an HTML document is returned that reports success in connecting to the host. On failure, an HTML document is returned that reports the error encountered in testing the host.

Detailed Description Text (272):

POST Results: On success, an HTML document is returned that contains the status that vPOS terminal was successfully. On failure, an HTML document is returned that reports the cause of failure of the operation, e.g., access denied, the vPOS terminal is already locked or is presently processing a transaction, etc.

Detailed Description Text (283):

POST Results: Currently, debit card based transactions are not supported. The result is an HTML document indicating the success or failure of the host logon operation.

Detailed Description Text (293):

POST Results: On success, the HTML document returned by the vPOS contains the values set by the merchant. On failure, the HTML document contains the reason for the failure of the invocation of the URL.

Detailed Description Text (303):

POST Results: On success, the POST modifies values of the terminal configuration table parameters. On failure, the HTML document contains the reason for the failure of the transaction.

Detailed Description Text (308):

GET Results: For a given transaction, the URL returns an HTML document. If a transaction refers to an older transaction, the transaction's entire history is made available.

Detailed Description Text (310):

Depending upon the method (GET/POST) as well as the success or failure of the HTTP request, different documents are returned to the user. The vPOS terminal provides a framework whereby different documents are returned based upon a number of preferences. Currently the language and content-type are supported as preferences.

Detailed Description Text (311):

A simple framework is proposed here. Each of the transaction has a set of documents associated with it: form for the payment transaction, GET success, GET failure, POST success, and POST failure.

Detailed Description Text (312):

In the directory structure defined below, documents are stored corresponding to the preferences. The top level of the directory structure is the content-type, the next level is language (for NLS support). For example, to create text/html content in U.S. English & French, the directory structure given below would contain the HTML documents for each of the transactions. The vPOS terminal cartridge has a configuration file that allows the user to specify the content-type as well as the language to be used for a cartridge. The first release

of the vPOS terminal cartridge supports one content-type and language for each server.

Detailed Description Text (1105):

Converts transaction data to legacy formats; forwards the mapped requests (in the clear) to a payment processor over existing communication links

Detailed Description Text (1106):

Converts transaction responses, correlates them with the original requests, and sends the mapped responses back to the merchants

Detailed Description Text (1143):

UC Berkeley Software Distribution 4.3 (BSD 4.3) including such features as job control, fast file system, symbolic links, long file names, and the C shell

Detailed Description Text (1144):

System V.4 File System Directory Layout

Detailed Description Text (1158):

SQL\*Net. The Gateway's Oracle7 database can be accessed by administration clients using SQL\*Net. Administration software can establish database connectivity to retrieve data for generating transaction reports.

Detailed Description Text (1162):

Gateway statistics about transaction requests (by transaction type) and transaction results (e.g., success, failed due to host, failed due to authentication, etc.) can be determined at any time for a particular time interval by generating a report.

Detailed Description Text (1164):

Basic Request/Response Mappings

Detailed Description Text (1165):

The following table shows the basic request/response mapping between the SET protocol and the LEGACY protocol.

Detailed Description Text (1166):

Detailed Message Field Mappings

Detailed Description Text (1175):

The following table itemizes the proposed mapping of LEGACY specific action codes and error code pairs to the canonical error codes that will be sent in the SET response messages. The canonical error response code values and descriptions were taken directly from "ISO 8583: 1987 section 4.3.8 Table 7".

Detailed Description Text (1178):

The following two sections detail a proposed mapping between the LEGACY protocol and two new VeriFone proprietary SET extensions: BalInq (Balance Inquiry) and BalRes (Balance Response). The BalInq request is used by vPOS to query the Gateway as to the transaction totals and BalRes is the response sent by the Gateway to vPOS.

Detailed Description Text (1180):

This section tackles general design considerations of the Gateway software and is not limited to LEGACY (unless specifically mentioned). The complete functional behavior of the Gateway will be described in a separate document.

Detailed Description Text (1211):

The Gateway must handle replay attacks as outlined previously in this document. If the Gateway receives a request that it has already received from vPOS there could be several possible dispositions:

Detailed Description Text (1243):

The processing of Internet-based payment transactions is a coordinated interaction between the Internet Transaction Gateway and the vPOS servers that is based on the following principles. A vPOS terminal, as the initiator of the payment transaction, is responsible for the round-trip logical closure of the transaction. vPOS will retry a transaction that has been initiated with

the Gateway but where the response for the request was never received from the Gateway. A vPOS terminal selects--out of a pre-assigned range--a Terminal-Id that is to be used by the Gateway in a request to the host processor. This data element must be transported from the vPOS to the Gateway along with the payment-related information. The Terminal-Ids must be unique among the concurrent vPOS instances on a vPOS server system. However, the Terminal-Ids have no history. For example, a subsequent Force Post transaction need not use the same Terminal-Id as the original Authorization transaction. The vPOS will be responsible for making sure that only one request is outstanding for the same <Merchant-id, Terminal-id> data elements from a vPOS server system. The Gateway does not know that a response was successfully received by vPOS. This means that the vPOS must be responsible for initiating any retry attempts. The Gateway never initiates a retry attempt with the host processor without an explicit retry request from vPOS. The Gateway when asked to retry a request with the host, performs a relational database look-up and delivers a response that has already been received from the host processor but was previously missed by vPOS. This behavior of the Gateway is also known as the "transaction response cache." The Gateway will need to know that a vPOS request is a retry of something already sent. The prior request may or may not have been received. A solution for determining the difference between a retry attempt and a new request was described earlier in this document. vPOS must understand the "canonical" error codes that it will receive via the Gateway and be able to initiate the proper recovery action and/or generate the appropriate user-interface dialog.

#### Detailed Description Text (1269):

FIG. 28 is a Consumer Payment Message Sequence Diagram in accordance with a preferred embodiment of the invention. The diagram presents the flow of messages between the consumer, the browser, the merchant system, the PayWindow application, and CPCL. This message flow describes the payment process from the time an order is completed and the consumer elects to pay, to the time the payment is approved and the receipt is returned to the consumer. The difference between the Native implementation and Java implementation of the PayWindow application is in the delivery of the order information to the PayWindow. Once the order information is received by the PayWindow, the flow of messages/data is the same for both implementations. In the case of the Native implementation, the order information is delivered via a MIME message. This MIME message is sent to the PayWindow by the browser via a document file. In the Java implementation, the order information is delivered to the PayWindow by an applet. The merchant system sends an applet with the order information to the browser which in turn delivers the order to the PayWindow. Once the order is received, the PayWindow interacts with the consumer and the Protocol modules for the completion of the payment process.

#### Detailed Description Text (1316):

FIG. 61 depicts a flow diagram for the GatewayClearSetRequestHandler routine. Execution begins in Step 5105. In Step 5110 an SET analysis routine is called to analyze the SET request, as will be more fully disclosed below. Step 5110 sets a status flag indicating the next stage to be performed by the Gateway. In Step 5120 the Gateway checks to see whether the status is set to indicate that a response should be provided to the user. If so, execution proceeds to Step 5190, which ends the request handling routine and returns control to a calling routine, which then provides a response to the user. Otherwise execution proceeds to Step 5130. In Step 5130, the Gateway checks to see if the status is set to indicate that forward translation is required. Forward translation is necessary to translate an outgoing message into a format that can be understood by the host computer. If forward translation is indicated, execution proceeds to Step 5135. In Step 5135, the outgoing message is forwarded translated, as more fully disclosed below with respect to FIG. 53. If no forward translation is indicated, for example, if an already-translated transaction is being retried, execution proceeds to Step 5140. In Step 5140, the Gateway checks to see if the next step is communication to the host. If so, the Gateway proceeds to Step 5145, and initiates host communication as will be more fully discussed below with respect to FIG. 54. If not, execution proceeds to Step 5150. In Step 5150, the Gateway checks to see whether reverse translation is indicated. Reverse translation translates a response from a host into a format useable by the calling routine. If reverse translation is indicated, execution proceeds to Step 5155, and the reverse translation is performed, as will be more fully discussed below with respect to FIG. 55. In any case, after either forward translation in Step 5135, host communication in Step 5145, or reverse translation in Step 5155, control returns to Step 5120 for further processing. As will be more fully disclosed below, the forward translation, host communication, and reverse translation routines manipulate status indicators to prevent the occurrence of an infinite loop.

#### Detailed Description Text (1321):

In Step 5240 the Gateway checks to see if the request had been marked stale in Step 5222. If so, it proceeds to Step 5242, exiting with an error condition. In Step 5245, the Gateway attempts to retrieve from the database a message corresponding to the current SET request, as will be fully disclosed below with respect to FIG. 59. Step 5260 checks to see whether the message was successfully retrieved from the database. If the message was not found in the database, this indicates that the SET request represents a new message, and control proceeds to Step 5270. In Step 5270 a new message representing the SET request is added to the database, as is more fully disclosed below with respect to FIG. 60. Because this is a new request, it must be processed from the beginning, including forward translation. Therefore, after the new message is added in Step 5270, control proceeds to Step 5275. In step 5275, where a status flag is set indicating that the next step to be performed for this message is for translation. If the message was found in Step 5260, this indicates that the request represents a request that is already in progress. Therefore, control proceeds to Step 5280 to update the database with current information representing the request status. The update process is described in further detail with respect to FIG. 61, below. Following Step 5280, control proceeds to Step 5282. In Step 5282 the Gateway checks to see the disposition in which the SET request was left as a result of partial processing. This is done, for example, by interrogating fields in the database record that indicate the steps that have already been performed for this request. In Step 5283, based upon this status information, the Gateway indicates the next stage of processing to be performed: either forward translation, reverse translation, or communication with the host. After this status has been set, whether for a new request in Step 5275, or for an already-existing request in Step 5283, control proceeds to Step 5290, which exits the AnalyzeSetRequest routine, returning control to Step 5110 in FIG. 51. The AnalyzeSetRequest routine as depicted in FIGS. 52A and 52B may be implemented using the following C++ code:

Detailed Description Text (1323):

FIG. 53 depicts the execution of the TranslateForward routine, which is called by Step 5135 in FIG. 51. Execution begins at Step 5310. In Step 5320, the Gateway forward-translates the request to prepare it for transmission to the host. Forward translation consists of packaging the fields in the request into a format that is understandable by the legacy system at the financial institution. The exact format of the translated request will vary from institution to institution. However, in general, the format will consist of a fixed length record with predetermined fields, using a standard character set such as ASCII or EBCDIC. In Step 5330, the Gateway checks to see whether the translation was successfully performed. If not control proceeds to Step 5340, which returns an error condition. If the translation was successful, control proceeds to Step 5350. In Step 5350, the Gateway sets a status flag to indicate that the next stage to be performed for this SET request is to proceed to host communication. This will be used in the next iteration of the Gw\_ClearSetRequestHandler routine as depicted in FIG. 51. After the status is set in Step 5350, the translate forward routine returns control in Step 5360.

Detailed Description Text (1326):

FIG. 54 depicts the step of host communication, as shown in Step 5145 in FIG. 51. Execution begins in Step 5400. In Step 5405 the Gateway obtains from the request object the string representing the request text. In Step 5410 it obtains the sequence number for the request. In Step 5415 the Gateway determines the current time, in order to record the time at which the request is made. In Step 5420 the Gateway sends the request to the host and waits for a response from the host. When a response is received, execution continues in Step 5425. In Step 5425, the Gateway again checks the current time, thereby determining the time at which a response was received. In Step 5430, the Gateway checks to see whether the communication was successfully performed. If a communication was not successful, the Gateway records that an error occurred in Step 5432. If the communication was successful, the Gateway, in Step 5435, indicates that the request was successfully sent and responded to. In Step 5437, the Gateway sets the response string based upon the response received in Step 5420. In Step 5439 the Gateway sets a status to indicate that reverse translation of the received response is required. Regardless of whether the communication was successful or unsuccessful, execution continues to Step 5450. In Step 5450, the database is updated with status information from the host communication. In Step 5490, control is returned to the calling routine.

Detailed Description Text (1329):

FIG. 55 depicts the operation of the TranslateReverse routine, as executed in Step 5155 in FIG. 51. Execution begins at Step 5500. In Step 5510 the Gateway reverse-translates the response received from the legacy system host. Reverse translation consists of extracting data from the data records received from the legacy system, and placing them in objects so that they are

useable by the Gateway. In Step 5520, the Gateway checks to verify that translation was successful. If translation was successful control proceeds to Step 5530, where a status flag is set indicating a successful translation. If translation was not successful, control proceeds to Step 5540, in which the Status Flag is set to indicate an unsuccessful translation. Regardless of whether translation was successful or unsuccessful, execution proceeds to Step 5550. In Step 5550, a status flag is set to indicate that the next stage for the request is to provide a response from the Gateway. This step is always executed, because, regardless of whether the translation or any other aspect of the transaction was successful, a response indicating either success or failure must be returned by the Gateway. Control then proceeds to Step 5590, in which the TranslateReverse routine returns control to the calling routine in FIG. 51. It will be seen that the TranslateForward routine in FIG. 53, the DoHostCommunication routine depicted in FIG. 54, and the TranslateReverse routine depicted in FIG. 55, each alter the status of the request. As a result as the loop depicted in FIG. 51 executes a particular request will proceed through all three stages and finally to exit in Step 5190.

#### Detailed Description Paragraph Table (28):

Communications Parameter Table (CPT) This table contains communications parameters information specific to an acquirer. The HDT and this table have a one-to-one mapping between them.

Attributes/	Field Bytes	Field Description/Comments	Primary AN(100)	Primary Host Address	Address
(Telephone number, IP address, etc.)			Secondary AN(100)	Secondary Host Address to be used if the	
Address Primary Address is busy or not available.			Tertiary AN(100)	Tertiary Host Address.	
Address Response I(2)	Time-out value (in seconds)	before which the Time-out vPOS should receive a response from the host.			

#### Detailed Description Paragraph Table (29):

Communications Parameter Table (CPT) This table contains communications parameters information specific to an acquirer. The HDT and this table have a one-to-one mapping between them.

#### **A New Model for Advanced Placement Delivery. (Technology Information)**

T H E Journal (Technological Horizons In Education), 27, 3, 1

Oct, 1999

ISSN: 0192-592X LANGUAGE: English RECORD TYPE: Fulltext; Abstract

WORD COUNT: 1293 LINE COUNT: 00112

ABSTRACT: Schools are faced with the problem of making Advanced Placement  
( **AP** ) curriculum available due lack of experienced teachers and enough  
students to create an economical class size. An Internet-based online  
distance learning program can meet both the needs of **AP** curriculum. In  
such a program, several students from all over the country can share a...

#### TEXT:

...preparatory coursework, schools are faced with two primary

challenges in providing a broad Advanced Placement ( **AP** ) curriculum. First, many schools do not have enough students to create an economical class size in most **AP** subject areas. Second, schools may not have an experienced teacher available to lead an **AP** course. ... taking up the challenge of providing a better distance learning experience for learners -- in particular, **AP** students. Their solutions take advantage of the power of Internet technologies to incorporate these key...

...Demand for Advanced Placement Increases

According to The College Board, the number of requests for **AP** exams is growing at a rate of 12 percent per year. Why?

Parents and students recognize the myriad advantages created by taking an **AP** course -- including a head start on college courses, increased college entrance competitiveness and opportunities for...

...organizations to call on secondary school educators to provide equal access to rigorous coursework and **AP** preparation.

Simultaneously, the nation is experiencing an "echo of the baby boom," which will soon...

...schools and colleges. As the number of students applying for admissions escalates, the demand for **AP** will increase and colleges will weigh **AP** credentials even more heavily in the admissions process.

Online **AP** Alternative

Internet-based distance learning can help answer this growing call for broader access to **AP** coursework. By combining experts in technology and education, an online distance learning program can provide...

...special funding programs to encourage schools to use this alternative to start or expand their **AP** programs.

A student's online **AP** experience might look like this: The student shares a virtual class with 20 to 25...

...informed if work falls below expectations or the level needed for successful completion of the **AP** exam.

This Internet-based distance learning course structure ensures that the key components of a...

...how they perform in those topics. The online instructor can print and review a computer- **generated report** and then talk with parents and school mentors about the student's performance.

Additional Benefits...

...expert teachers and subject experts. For instance, at APEX Online Learning, a team of seasoned **AP** teachers and subject experts who understand the students, the exam and the subject, work together...in most educational applications, technology alone will not solve every challenge of providing access to **AP** courses. Internet-based distance learning, however, does offer schools a practical alternative for providing their...
